

# What is Persistent Homology?

# What This Presentation Will Do

- I will give an intuitive explanation of persistent homology, the main technique of topological data analysis
  - Topological data analysis studies the shape (qualitative features) of datasets with tools from topology
- My project itself will be coding an algorithm to compute persistent homology, but this presentation will largely explain what persistent homology is
- This corresponds to what I've done in the project so far - next steps are to understand and program the algorithm
- I'll start by provide some background about topology - the presentation aims to capture key concepts intuitively rather than working through the material technically

# Topology

Some classic continuous deformations  
(homeomorphisms)

Gif source:

<https://en.wikipedia.org/wiki/Topology>

# Topology

- Topology studies qualitative features of spaces
- Typically these are topological properties, which are properties that are invariant under homeomorphism
- A common type of example is loops/holes
  - A circle is a 1-dimensional hole, a sphere a 2-dimensional hole
- We can detect these with something called homology, which misses a lot of features that homeomorphism can detect

# Triangulation

- Homology is defined via a *triangulation*, or a homeomorphism from the topological space of interest to something called a *simplicial complex*

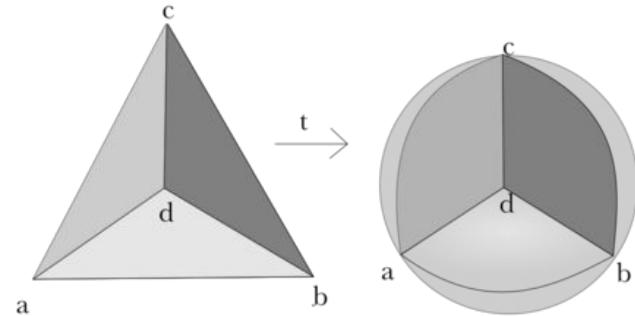

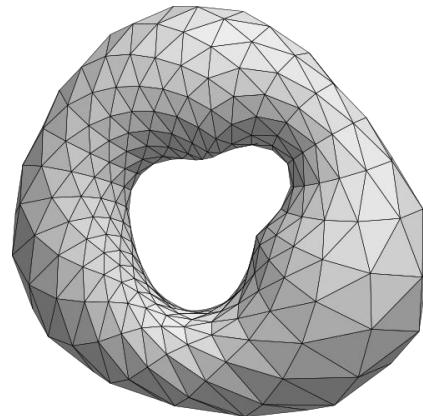

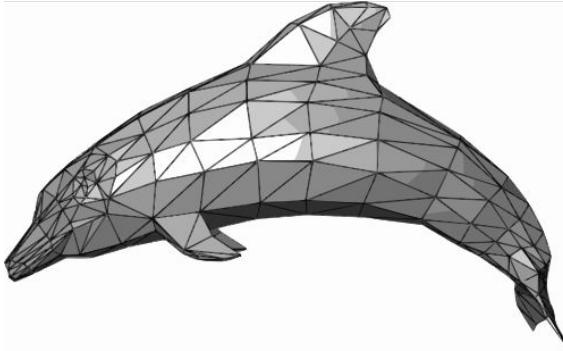

Image source: [https://en.wikipedia.org/wiki/Triangulation\\_\(topology\)](https://en.wikipedia.org/wiki/Triangulation_(topology))

# Triangulation: Simplices

- Simplicial complexes are made up of simplices (or simplexes)
- We can (a little loosely) define simplices inductively: a 0-simplex is a point, and a  $k+1$  simplex is taken by adding a vertex to a  $k$ -simplex and connecting it to all the points of the  $k$ -simplex

Image source: <https://en.wikipedia.org/wiki/Simplex>

# Triangulation: Simplicial Complex

- Simplicial complexes are made by attaching a bunch of simplices at their faces (subsimplices)

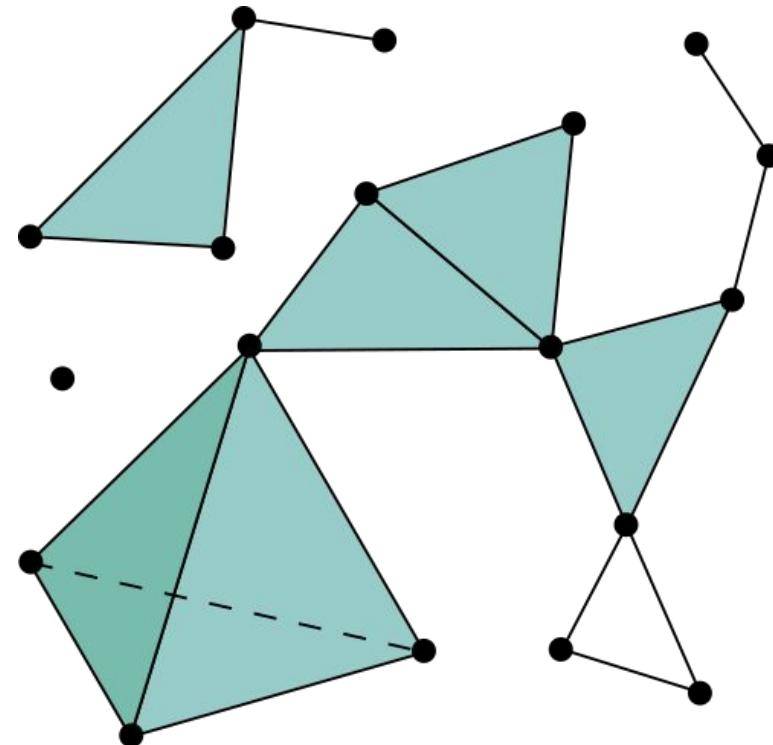

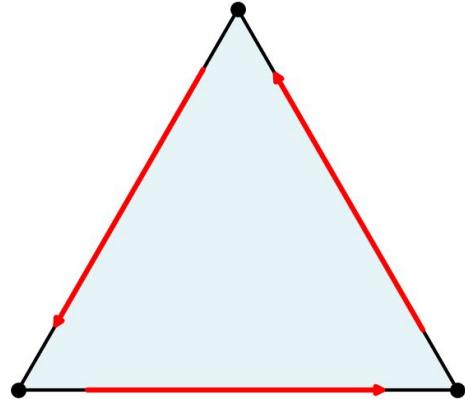

Image source: [https://en.wikipedia.org/wiki/Simplicial\\_complex](https://en.wikipedia.org/wiki/Simplicial_complex)

# Cycles and Boundaries

**This 1-cycle IS a boundary**

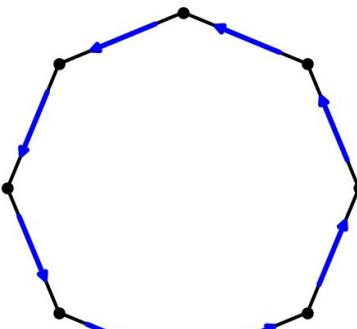

(in  $B_1$ , not essential)

$$\partial_2(\sigma) = [v_1, v_2] - [v_0, v_2] + [v_0, v_1]$$

**This 1-cycle is NOT a boundary**

(in  $Z_1$  but not  $B_1$ , essential!!)

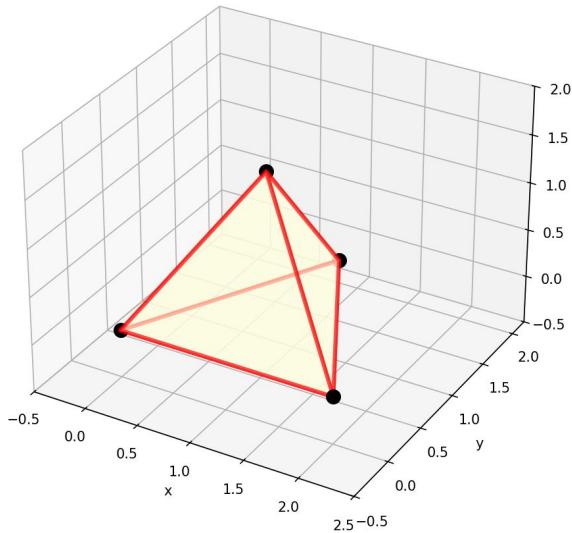

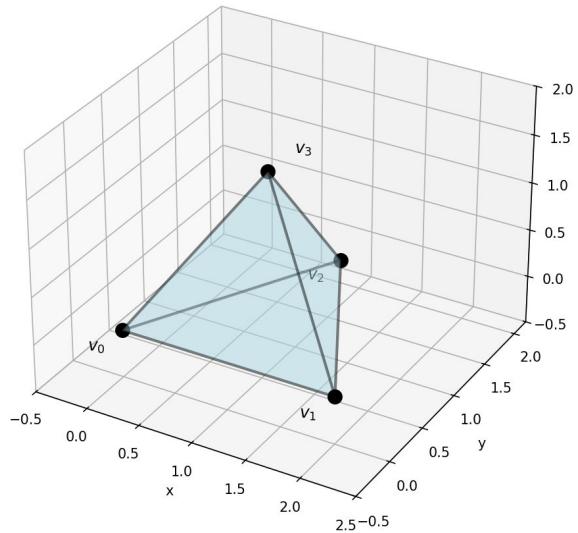

$$\partial_1(\text{cycle}) = 0$$

# Cycles and Boundaries

3-simplex  $\tau$  (solid tetrahedron)

$\partial_3(\tau) = \text{surface (2-cycle)}$   
This 2-cycle IS a boundary

The 4 faces form a 2-cycle (closed surface) that bounds the solid interior

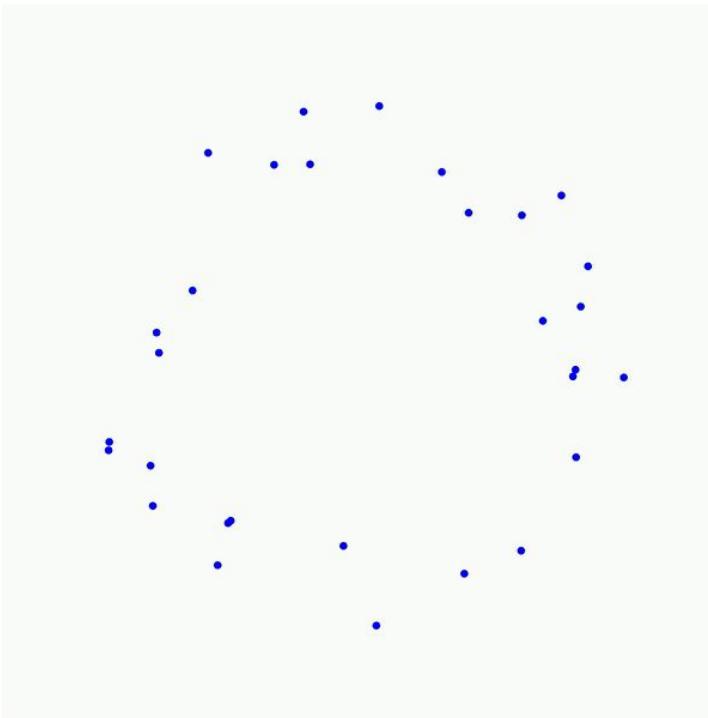

# Homology

- Key insight: loops/holes in a space correspond to cycles that are **not boundaries** in that space's triangulation
- Something called a *homology group* keeps track of the structure of cycles that are not boundaries
- You will have different homology groups for different dimensions, corresponding to the differing dimensions of loops

# Recap

- This project is in topological data analysis, which analyzes data by computing qualitative features of the data with topological tools
- We are specifically looking for loops/holes in data, which we can find by triangulating our space, then finding homology groups by finding the boundaries and cycles of the corresponding complex
- Two hanging questions: how do we triangulate a data set, and what is *persistent* homology? The answer to the first will prompt the answer to the second

# Vietoris-Rips Complex

- Given a distance  $d$ , we will include a simplex of a set of points iff all points in the set have distance at most  $d$
- We can see that increasing  $d$  will increase the connectivity of our complex
- Low  $d \rightarrow$  seeing loops that are just noise
- High  $d \rightarrow$  not seeing any loops
- How we can detect underlying shape in light of this?

# Persistent Homology

- Persistent homology tracks the “persistence” of holes in the data across varying values of  $d$
- This produces a “barcode” diagram that allows us to visually inspect the structure of the data

# Persistence Barcodes

- $H_1$  is the group of 1-d loops (like a circle),  $H_2$  the group of 2-d loops (like a sphere),  $H_0$  unfortunately disanalogously the set of connected components
